The American College of Radiology, with more than 30,000 members, is the principal organization of radiologists, radiation oncologists, and clinical medical physicists in the United States. The College is a nonprofit professional society whose primary purposes are to advance the science of radiology, improve radiologic services to the patient, study the socioeconomic aspects of the practice of radiology, and encourage continuing education for radiologists, radiation oncologists, medical physicists, and persons practicing in allied professional fields.

The American College of Radiology will periodically define new practice parameters and technical standards for radiologic practice to help advance the science of radiology and to improve the quality of service to patients throughout the United States. Existing practice parameters and technical standards will be reviewed for revision or renewal, as appropriate, on their fifth anniversary or sooner, if indicated.

Each practice parameter and technical standard, representing a policy statement by the College, has undergone a thorough consensus process in which it has been subjected to extensive review and approval. The practice parameters and technical standards recognize that the safe and effective use of diagnostic and therapeutic radiology requires specific training, skills, and techniques, as described in each document. Reproduction or modification of the published practice parameter and technical standard by those entities not providing these services is not authorized.

Amended 2014 (Resolution 39)*

**ACR–ASNR–SPR PRACTICE PARAMETER FOR THE PERFORMANCE AND INTERPRETATION OF MAGNETIC RESONANCE IMAGING (MRI) OF THE BRAIN**

**PREAMBLE**

This document is an educational tool designed to assist practitioners in providing appropriate radiologic care for patients. Practice Parameters and Technical Standards are not inflexible rules or requirements of practice and are not intended, nor should they be used, to establish a legal standard of care. For these reasons and those set forth below, the American College of Radiology and our collaborating medical specialty societies caution against the use of these documents in litigation in which the clinical decisions of a practitioner are called into question.

The ultimate judgment regarding the propriety of any specific procedure or course of action must be made by the practitioner in light of all the circumstances presented. Thus, an approach that differs from the guidance in this document, standing alone, does not necessarily imply that the approach was below the standard of care. To the contrary, a conscientious practitioner may responsibly adopt a course of action different from that set forth in this document when, in the reasonable judgment of the practitioner, such course of action is indicated by the condition of the patient, limitations of available resources, or advances in knowledge or technology subsequent to publication of this document. However, a practitioner who employs an approach substantially different from the guidance in this document is advised to document in the patient record information sufficient to explain the approach taken.

The practice of medicine involves not only the science, but also the art of dealing with the prevention, diagnosis, alleviation, and treatment of disease. The variety and complexity of human conditions make it impossible to always reach the most appropriate diagnosis or to predict with certainty a particular response to treatment. Therefore, it should be recognized that adherence to the guidance in this document will not assure an accurate diagnosis or a successful outcome. All that should be expected is that the practitioner will follow a reasonable

---

1 Iowa Medical Society and Iowa Society of Anesthesiologists v. Iowa Board of Nursing, ___ N.W.2d ___ (Iowa 2013) Iowa Supreme Court refuses to find that the ACR Technical Standard for Management of the Use of Radiation in Fluoroscopic Procedures (Revised 2008) sets a national standard for who may perform fluoroscopic procedures in light of the standard’s stated purpose that ACR standards are educational tools and not intended to establish a legal standard of care. See also, Stanley v. McCarver, 63 P.3d 1076 (Ariz. App. 2003) where in a concurring opinion the Court stated that “published standards or guidelines of specialty medical organizations are useful in determining the duty owed or the standard of care applicable in a given situation” even though ACR standards themselves do not establish the standard of care.
course of action based on current knowledge, available resources, and the needs of the patient to deliver effective and safe medical care. The sole purpose of this document is to assist practitioners in achieving this objective.

I. INTRODUCTION

This practice parameter was revised collaboratively by the American College of Radiology (ACR), the American Society of Neuroradiology (ASNR), and the Society for Pediatric Radiology (SPR).

Magnetic resonance imaging (MRI) of the brain is a proven and well-established imaging modality in the evaluation and assessment of normal and abnormal conditions of the brain. MRI of the brain is the most sensitive technique available because of its high sensitivity in exploiting inherent contrast differences of tissues as a result of variable magnetic relaxation properties and magnetic susceptibilities. MRI is a rapidly changing technology, and ongoing technical improvements will continue to improve MRI diagnosis of brain disorders. This practice parameter outlines the principles for performing high-quality MRI of the brain.

II. INDICATIONS

Indications for MRI of the brain include, but are not limited to:

1. Neoplastic conditions or other mass or mass like conditions of the brain parenchyma, meninges or cranium, either primary or secondary [1-8].
2. Vascular
   a. Acute ischemia and infarction [9-13].
   b. Chronic vascular disease [14-16].
   c. Vascular malformations such as developmental venous anomaly, cavernous angioma, arteriovenous malformation, arteriovenous fistulas and aneurysm [17-20].
   d. Arterial or venous/dural venous sinus abnormalities, including congenital and acquired disorders and thrombosis [21,22].
   e. Additionally, magnetic resonance angiography (MRA) may provide more detailed noninvasive vascular information. (See the ACR–ASNR–SNIS–SPR Practice Parameter for the Performance of Cervicocerebral Magnetic Resonance Angiography [MRA].)
3. Congenital disorders and anatomical abnormalities including the evaluation of brain maturation [23-26].
4. Congenital or acquired neurodegenerative disorders [14,27-30].
5. Congenital or acquired hydrocephalus [31,32].
6. Metabolic disorders [33,34].
7. Trauma [35-38].
   a. Certain benefits over computed tomography (CT), such as detection of diffuse axonal injury.
   c. Nonaccidental trauma.
8. Hemorrhage.
   a. Certain benefits over CT, such as determining the age of hemorrhages, evaluation of chronic hemorrhage, and detection of microhemorrhages [39,40].
   b. MRI with gradient echo axial imaging has sensitivity comparable to that of CT in specific settings such as the rapid evaluation of acute ischemic stroke [41].
9. Inflammatory and autoimmune disorders including disorders of myelination [42-45].
10. Infectious disorders: encephalitis, meningitis, abscess [46-49].
11. Endocrine disorders [50,51].
12. Evaluation of the cranial nerves [52].
13. Epilepsy and movement disorders [30,53-57].
14. Psychiatric disorders [58].
15. Follow-up of treatment including iatrogenic sequelae such as radiation necrosis [59-62].
16. Image guidance for treatment planning, surgery, or interventional [63-65]. (See the ACR–ASNR Practice Parameter for the Performance of Non-Breast MRI-Guided Procedures.)
Extended indications for brain MRI include techniques that provide additional real-time, dynamic or quantitative information that assists in therapeutic guidance or decision-making.

1. CSF flow, blood flow, and brain perfusion [13,31,32,56,67].
2. Spectroscopy [10,34,67-71].
3. Functional imaging [63,72-75].
4. Volumetry [14,28,66].
5. Morphometry [57,58,77].
6. Tractography [26,78-81].
7. Combination with positron emission tomography [82-84].

III. QUALIFICATIONS AND RESPONSIBILITIES OF PERSONNEL

See the ACR Practice Parameter for Performing and Interpreting Magnetic Resonance Imaging (MRI).

IV. SAFETY GUIDELINES AND POSSIBLE CONTRAINDICATIONS

See the ACR Practice Parameter for Performing and Interpreting Magnetic Resonance Imaging (MRI), the ACR Manual on Contrast Media, and the ACR Guidance Document on MR Safe Practices.

Peer-reviewed literature pertaining to MR safety should be reviewed on a regular basis.

V. SPECIFICATIONS OF THE EXAMINATION

The supervising physician must have complete understanding of the indications, risks, and benefits of the examination, as well as alternative imaging procedures [85-88]. The physician must be familiar with potential hazards associated with MRI, including potential adverse reactions to contrast media. The physician should be familiar with relevant ancillary studies that the patient may have undergone. (See the ACR Practice Parameter for Communication of Diagnostic Imaging Findings.) The physician performing MRI interpretation must have a clear understanding and knowledge of the anatomy and pathophysiology relevant to the MRI examination.

The clinical request form should be initiated by the referring physician or any appropriate allied health care professional acting within his or her scope of practice. It should contain pertinent information regarding the clinical indication for the procedure.

The written or electronic request for MRI of the brain should provide sufficient information to demonstrate the medical necessity of the examination and allow for its proper performance and interpretation.

Documentation that satisfies medical necessity includes 1) signs and symptoms and/or 2) relevant history (including known diagnoses). Additional information regarding the specific reason for the examination or a provisional diagnosis would be helpful and may at times be needed to allow for the proper performance and interpretation of the examination.

The request for the examination must be originated by a physician or other appropriately licensed health care provider. The accompanying clinical information should be provided by a physician or other appropriately licensed health care provider familiar with the patient’s clinical problem or question and consistent with the state scope of practice requirements. (ACR Resolution 35, adopted in 2006)

The supervising physician must also understand the pulse sequences to be used and their effect on the appearance of the images, including the potential generation of image artifacts. Standard imaging protocols may be established and varied on a case-by-case basis when necessary. These protocols should be reviewed and updated periodically.
A. Patient Selection

The physician responsible for the examination should supervise patient selection and preparation, and be available in person or by phone for consultation. Patients and all other persons entering the MRI safety zone (employees and nonemployees) must be screened and interviewed (when their condition permits) prior to the examination to exclude individuals who may be at risk by exposure to the MRI environment.

Certain indications require administration of intravenous (IV) contrast media. IV contrast enhancement should be performed using appropriate injection protocols and in accordance with the institution’s policy on IV contrast utilization. Patients receiving intravenous gadolinium chelates should be evaluated for risk factors or contraindications to intravenous MRI contrast media, especially the potential risk of nephrogenic systemic fibrosis (NSF) [89]. (See the ACR–SPR Practice Parameter for the Use of Intravascular Contrast Media, the ACR Manual on Contrast Media, the ACR Guidance Document on MR Safe Practices, and the ACR website.)

Patients suffering from anxiety or claustrophobia may require sedation or additional assistance. Sedation of pediatric patients (and in some cases nonsedated patients) may benefit from child life support staff. Administration of anxiolytics or moderate sedation may be needed to achieve a successful examination. If moderate sedation is necessary, refer to the ACR–SIR Practice Parameter for Sedation/Analgesia.

B. Facility Requirements

Appropriate emergency equipment and medications must be immediately available to treat adverse reactions associated with administered medications. The equipment and medications should be monitored for inventory and drug expiration dates on a regular basis. The equipment, medications, and other emergency support must also be appropriate for the range of ages and sizes in the patient population.

C. Examination Technique

MRI examination of the brain can be performed on closed and open MRI systems of various field strengths, using a local surface coil (head coil), and with a wide array of pulse sequences [8,10,12,23,25,29,30,32,44,45,49,50,67,73,74,90-108]. This is a rapidly evolving field, and the appropriate pulse sequences and plane of imaging must be individualized and tailored to the clinical question at hand under the supervision of the MRI physician. The most commonly accepted basic imaging protocols for MRI of the brain currently include a T1-weighted sequence in the sagittal plane (or a T1-weighted volumetric acquisition), and T2-weighted fluid-attenuated inversion recovery (FLAIR) and fast spin-echo or turbo-spin-echo (or equivalent) sequences in the axial plane. If FLAIR is not available or in children under the age of 2 years, proton density weighted sequences may be helpful. Under certain clinical circumstances, very rapid acquisitions such as echo planar imaging or single shot fast-spin-echo imaging can be performed to obtain T2 information. Diffusion imaging, if available, is helpful in many indications. The entire brain should be covered in the respective axial and/or coronal and/or sagittal imaging planes. (See the ACR MRI Accreditation Program Clinical Image Quality Guide.)

The recovery time (TR) and echo time (TE) required to optimize image quality depends on the field strength of the magnet. These parameters must therefore be adjusted by the supervising physician for image optimization. For example, lower-field-strength magnets may require lower TRs, while higher-field-strength magnets may require longer TRs for image optimization.

Slice thickness, spatial resolution, signal-to-noise ratio, acquisition time, and contrast are all interrelated. To optimize spatial resolution, imaging of the brain should be performed with a slice thickness of no greater than 5 mm and an interslice gap of no greater than 2.5 mm. Thinner slices (less than 5 mm) and smaller interslice gaps (less than 2.5 mm) may provide superior image detail, if clinical circumstances warrant.

Gadolinium chelates may be administered intravenously when there is suspicion of breakdown of the blood-brain barrier [6,109-112]. Postcontrast images should be obtained in at least one plane, but preferably two or more
perpendicular planes, with one plane being the same as the precontrast series, with short TR and TE sequences (T1-weighted). (Alternatively one postcontrast series could be obtained using a T1-weighted volumetric acquisition). Postcontrast FLAIR images may add value in the assessment of leptomeningeal disease [113].

With the advent of high-performance gradient coil assemblies and amplifiers and other technical enhancements, advanced imaging applications are also an option when the appropriate hardware and software exist. Improvements in the receiver and data acquisition systems also allow for more rapid imaging. Higher-field-strength MR (e.g., 3T and 7T) may provide added utility in some clinical situations [53,114-120].

While a detailed discussion of all the evolving advanced imaging techniques is beyond the scope of this practice parameter, it should be noted that rapid pulse sequences and other advanced imaging techniques may provide added value for MRI of the brain. These can include, but are not limited to echo planar imaging [121], parallel imaging [29,91,100,122,123], diffusion weighted imaging [45,90,93,124-130], diffusion tensor imaging [25,26,79,80,91,104,128,131-134], rapid gradient-echo pulse sequences (capable of providing T1 or T2 information and enabling 3D acquisitions) [135], susceptibility weighted imaging [136-142], functional imaging [131,143-158], perfusion imaging [159-166], volumetric [32,167-171], morphometric [172-182] magnetic source imaging [183], and other quantitative applications [128,184-194]. When considering T1- and/or T2-weighted 3D image acquisitions, it is essential to weigh benefits of efficiency against levels of diagnostic confidence. The latter may vary widely across imaging providers and may require extensive testing and consensus before implementing 3D sequences into diagnostic imaging protocols.

Certain clinical circumstances may warrant the use of proton MR spectroscopy [68-70,195-201] as an adjunct to routine MR brain imaging. (See the ACR–ASNR–SPR Practice Parameter for the Performance and Interpretation of Magnetic Resonance Spectroscopy of the Central Nervous System.) Additional techniques that may be useful under the appropriate clinical circumstances include 3-dimensional imaging techniques [202-205], neuronavigation and intraoperative MRI [64,96,105,206], magnetization transfer imaging [207-211], cerebral spinal fluid (CSF) flow study using phase-contrast pulse sequences [212], and variations of single shot fast-spin-echo or turbo spin-echo imaging.

It is the responsibility of the supervising physician to determine whether additional pulse sequences or nonconventional pulse sequences and imaging techniques confer added benefit for the diagnosis and management of the patient. Generally MRI examination of the brain should be performed within parameters approved by the Food and Drug Administration (FDA). Examinations that use techniques not approved by the FDA can be considered when they are judged to be medically appropriate.

VI. DOCUMENTATION

Reporting should be in accordance with the ACR Practice Parameter for Communication of Diagnostic Imaging Findings.

VII. EQUIPMENT SPECIFICATIONS

The MRI equipment specifications and performance must meet all state and federal requirements. The requirements include, but are not limited to, specifications of maximum static magnetic strength, maximum rate of change of magnetic field strength (dB/dt), maximum radiofrequency power deposition (specific absorption rate), and maximum acoustic noise levels [213].

VIII. QUALITY CONTROL AND IMPROVEMENT, SAFETY, INFECTION CONTROL, AND PATIENT EDUCATION

Policies and procedures related to quality, patient education, infection control, and safety should be developed and implemented in accordance with the ACR Policy on Quality Control and Improvement, Safety, Infection Control,
Specific policies and procedures related to MRI safety should be in place with documentation that is updated annually and compiled under the supervision and direction of the supervising MRI physician. Guidelines should be provided that deal with potential hazards associated with the MRI examination of the patient as well as to others in the immediate area. Screening forms must also be provided to detect those patients who may be at risk for adverse events associated with the MRI examination.

Equipment monitoring should be in accordance with the ACR–AAPM Technical Standard for Diagnostic Medical Physics Performance Monitoring of Magnetic Resonance Imaging (MRI) Equipment.

ACKNOWLEDGEMENT

This guideline was revised according to the process described under the heading The Process for Developing ACR Practice Guidelines and Technical Standards on the ACR website (http://www.acr.org/guidelines) by the Guidelines and Standards Committees of the ACR Commissions on Neuroradiology and Pediatric Radiology in collaboration with the ASNR and the SPR.

Collaborative Committee – members represent their societies in the initial and final revision of this guideline
