The American College of Radiology, with more than 30,000 members, is the principal organization of radiologists, radiation oncologists, and clinical medical physicists in the United States. The College is a nonprofit professional society whose primary purposes are to advance the science of radiology, improve radiologic services to the patient, study the socioeconomic aspects of the practice of radiology, and encourage continuing education for radiologists, radiation oncologists, medical physicists, and persons practicing in allied professional fields.

The American College of Radiology will periodically define new practice parameters and technical standards for radiologic practice to help advance the science of radiology and to improve the quality of service to patients throughout the United States. Existing practice parameters and technical standards will be reviewed for revision or renewal, as appropriate, on their fifth anniversary or sooner, if indicated.

Each practice parameter and technical standard, representing a policy statement by the College, has undergone a thorough consensus process in which it has been subjected to extensive review and approval. The practice parameters and technical standards recognize that the safe and effective use of diagnostic and therapeutic radiology requires specific training, skills, and techniques, as described in each document. Reproduction or modification of the published practice parameter and technical standard by those entities not providing these services is not authorized.

Revised 2013 (Resolution 29)*

ACR PRACTICE PARAMETER FOR THE PERFORMANCE OF ESOPHAGRAMS AND UPPER GASTROINTESTINAL EXAMINATIONS IN ADULTS

PREAMBLE

This document is an educational tool designed to assist practitioners in providing appropriate radiologic care for patients. Practice Parameters and Technical Standards are not inflexible rules or requirements of practice and are not intended, nor should they be used, to establish a legal standard of care. For these reasons and those set forth below, the American College of Radiology and our collaborating medical specialty societies caution against the use of these documents in litigation in which the clinical decisions of a practitioner are called into question.

The ultimate judgment regarding the propriety of any specific procedure or course of action must be made by the physician or medical physicist in light of all the circumstances presented. Thus, an approach that differs from the practice parameters, standing alone, does not necessarily imply that the approach was below the standard of care. To the contrary, a conscientious practitioner may responsibly adopt a course of action different from that set forth in the practice parameters when, in the reasonable judgment of the practitioner, such course of action is indicated by the condition of the patient, limitations of available resources, or advances in knowledge or technology subsequent to publication of the practice parameters. However, a practitioner who employs an approach substantially different from these practice parameters is advised to document in the patient record information sufficient to explain the approach taken.

The practice of medicine involves not only the science, but also the art of dealing with the prevention, diagnosis, alleviation, and treatment of disease. The variety and complexity of human conditions make it impossible to always reach the most appropriate diagnosis or to predict with certainty a particular response to treatment. Therefore, it should be recognized that adherence to these practice parameters will not assure an accurate diagnosis or a successful outcome. All that should be expected is that the practitioner will follow a reasonable course of action based on current knowledge, available resources, and the needs of the patient to deliver effective

---

1 Iowa Medical Society and Iowa Society of Anesthesiologists v. Iowa Board of Nursing, ___ N.W.2d ___ (Iowa 2013) Iowa Supreme Court refuses to find that the ACR Technical Standard for Management of the Use of Radiation in Fluoroscopic Procedures (Revised 2008) sets a national standard for who may perform fluoroscopic procedures in light of the standard’s stated purpose that ACR standards are educational tools and not intended to establish a legal standard of care. See also, Stanley v. McCarver, 63 P.3d 1076 (Ariz. App. 2003) where in a concurring opinion the Court stated that “published standards or guidelines of specialty medical organizations are useful in determining the duty owed or the standard of care applicable in a given situation” even though ACR standards themselves do not establish the standard of care.
and safe medical care. The sole purpose of these practice parameters is to assist practitioners in achieving this objective.

I. INTRODUCTION

Single-contrast and double-contrast (biphasic) examinations are proven and useful procedures for evaluating the esophagus and the upper gastrointestinal (GI) tract \[1-13\]. Their goal is to establish the presence or absence, nature, and extent of disease with a diagnostic-quality study, using the minimum radiation dose necessary. The following practice parameters are for performing these examinations in adult patients.

II. INDICATIONS AND CONTRAINDICATIONS

A. Indications for Esophagram

1. Pertinent history and symptoms serving as indications for an esophagram include, but are not limited to:
   a. Atypical chest pain felt to be unrelated to cardiac or pulmonary disease.
   b. Symptomatic or suspected gastroesophageal reflux \[2-4,7,8,10,11\].
   c. Dysphagia.
   d. Odynophagia.

2. The esophagram is helpful in the diagnosis and evaluation of many conditions, including, but not limited to:
   a. Suspected or known motility disorders \[2,4,7,8,10\].
   b. Esophagitis \[2-4,7,8,10,11\].
   c. Strictures \[2-4,7,8,10\].
   d. Varices \[7,8\].
   e. Suspected esophageal perforation \[7,14,15\].
   f. Neoplasms \[3,4,7,8,10\].
   g. Esophageal obstruction \[2-4,7,8,10\].
   h. Postoperative assessment \[14,15\].
   i. Suspected foreign body.

B. Indications for Upper GI Examination

1. History and symptoms serving as indications for an upper GI examination include, but are not limited to:
   a. Symptomatic or suspected gastroesophageal reflux \[2-4,7,8,10,11\].
   b. Abdominal pain.
   c. Epigastric distress or discomfort.
   d. Dyspepsia.
   e. Nausea.
   f. Vomiting.
   g. Signs and/or symptoms of upper GI bleeding.
   h. Anemia.
   i. Weight loss.

2. The upper GI examination is helpful in the diagnosis and evaluation of many conditions, including, but not limited to:
   a. Suspected or known gastritis or duodenitis \[13\].
   b. Peptic ulcer disease \[1,5,6,12,13\].
   c. Hiatal hernia \[7,8\].
   d. Varices \[12\].
   e. Suspected perforation \[14,15\].
   f. Neoplasms \[7,9\].
   g. Gastric outlet obstruction \[12\].
Esophagrams and upper GI examinations may be indicated to evaluate anatomy in postsurgical patients for detecting spontaneous, post-traumatic, or postsurgical leaks from the esophagus, stomach, or duodenum. If a leak or perforation is clinically suspected, water-soluble contrast should be used for the initial evaluation. If aspiration or esophageal-tracheal or bronchial fistula is suspected, iso-osmolar or low-osmolar contrast or barium agents should be considered. (See section IV C.5)

For the pregnant or potentially pregnant patient, see the ACR–SPR Practice Parameter for Imaging Pregnant or Potentially Pregnant Adolescents and Women with Ionizing Radiation [16].

C. Contraindications

Patients who have undergone recent esophageal or gastric surgery or recent trauma, or who are unable to cooperate with the examination are not candidates for a double-contrast examination. Relevant patient history should be obtained prior to the procedure to determine the appropriate type of procedure and contrast medium.

III. QUALIFICATIONS OF PERSONNEL

For qualifications of physicians, medical physicists, radiologist assistants, and radiologic technologists, see the ACR–SPR Practice Parameter for General Radiography [17].

IV. SPECIFICATIONS OF THE EXAMINATION

The written or electronic request for an esophagram and upper GI examination should provide sufficient information to demonstrate the medical necessity of the examination and allow for its proper performance and interpretation.

Documentation that satisfies medical necessity includes 1) signs and symptoms and/or 2) relevant history (including known diagnoses). Additional information regarding the specific reason for the examination or a provisional diagnosis would be helpful and may at times be needed to allow for the proper performance and interpretation of the examination.

The request for the examination must be originated by a physician or other appropriately licensed health care provider. The accompanying clinical information should be provided by a physician or other appropriately licensed health care provider familiar with the patient’s clinical problem or question and consistent with the state scope of practice requirements. (ACR Resolution 35, adopted in 2006)

A. Patient Preparation

For a routine esophagram the patient should be instructed to refrain from taking anything by mouth for a minimum of 2 hours before the procedure. For an upper GI examination, the patient should be instructed to refrain from taking anything by mouth after midnight the night before. Examinations may be performed with shorter fasting times as clinically indicated. Patients may generally take scheduled medications on the morning of the examination.

B. Examination Preliminaries

An appropriate medical history should be available, including the findings of laboratory tests and imaging, and the results of endoscopic and surgical procedures as applicable.
A preliminary (“scout”) image of the abdomen is often useful, particularly in postsurgical patients for delineation of staple lines. A preliminary image of the chest may be obtained prior to an esophagram.

C. Examination Technique

The physician should tailor the examination procedure to the individual patient as warranted by clinical circumstances and the condition of the patient to produce a diagnostic quality examination. Images should be manually collimated as much as possible in order to limit radiation exposure to the patient.

1. Single-contrast esophagram

   a. Using a low density (60% weight per volume [weight/volume]) barium suspension, the anatomic structure and motility of the entire esophagus should be evaluated fluoroscopically. Appropriate spot images should be obtained to document normal and abnormal findings. The examination should include barium-distended and, when appropriate, collapsed mucosal relief views of the esophagus, including fluoroscopic evaluation of motility. This is optimally performed with the patient in the prone or the prone right anterior oblique position, depending on the patient’s condition and the presence of risk factors such as the potential for aspiration. Specific views of the esophagogastric junction should also be included.

   b. Fluoroscopic assessment for gastroesophageal reflux should be performed.

   c. If the patient has symptoms suggesting swallowing dysfunction, then rapid sequence images or video recording for evaluating the pharynx and cervical esophagus should be considered. (See also the ACR Practice Parameter for the Performance of the Modified Barium Swallow [18].)

   d. For a patient with solid food dysphagia, a barium tablet or other solid food bolus may be given whenever possible, and passage should be observed with the patient in an upright position [7]. Water or barium may be given to assist passage. Symptoms should be reported.

   e. At the end of the examination, overhead images can be obtained as part of the routine protocol.

   f. The quality control indicators specific to this study are:

      i. Fluoroscopic observation of the entire esophagus while distended with barium, with appropriate spot images to document normal and abnormal findings.

      ii. Sufficient radiographic technique to penetrate the barium-filled esophagus on images.

      iii. Visualization of the gastroesophageal junction to exclude local pathology.

2. Double-contrast (biphasic) esophagram

   a. An effervescent agent that releases carbon dioxide into the lumen of the stomach should be administered to provide distention, if the patient can tolerate this agent.

   b. Fluoroscopic observation of the esophagus and gastric cardia and fundus should be performed in double contrast using a high-density (210% to 250% weight/volume) barium suspension with the patient in an upright oblique position. Appropriate spot images should be taken to document normal and abnormal findings.

   c. Fluoroscopic observation of esophageal motility and the distended esophagus should be performed using single-contrast technique while the patient is drinking barium and in a prone-oblique position. Appropriate spot images should be obtained as described above.

   d. Fluoroscopic assessment for gastroesophageal reflux should be performed.

   e. If the patient has symptoms suggesting a swallowing function abnormality, then rapid sequence imaging or video recording for evaluating the pharynx and cervical esophagus should be considered.

   f. For a patient with solid food dysphagia, a barium tablet or other solid food bolus may be given whenever possible, and passage should be observed with the patient in an upright position [7]. Water or barium may be given to assist passage. Symptoms should be reported.

   g. At the end of the examination, overhead images can be obtained as part of the routine protocol.

   h. The quality control indicators specific to this study are:
i. Fluoroscopic observation of the entire esophagus by both single-contrast and double-contrast techniques, with appropriate spot images to document normal and abnormal findings.

ii. A double-contrast view of the gastric cardia and fundus to exclude pathologic conditions in this adjacent anatomic region.

iii. Sufficient radiographic technique to penetrate the barium-filled esophagus.

3. Single-contrast upper GI examination

a. Fluoroscopic assessment of the morphology and function of the entire esophagus, stomach, and duodenum should be performed. A sufficient number of spot images should be obtained to adequately document normal and abnormal findings. Suggested views include barium-distended and, when appropriate, collapsed mucosal relief views of the esophagus, as well as barium-distended, mucosal relief, and/or compression views of the stomach and duodenum. At the end of the examination, overhead images can be obtained as part of the routine protocol.

b. The quality control indicators specific to this study are radiographic technique and graded compression that permit radiographic penetration of the barium suspension in the areas being examined.

4. Double-contrast (biphasic) upper GI examination

a. A hypotonic agent may be used to induce gastric and duodenal hypotonia.

b. An effervescent agent that releases carbon dioxide into the lumen of the stomach should be administered to provide distention.

c. After ingestion of high-density barium, fluoroscopy should be used to visualize all segments of the esophagus, stomach, and duodenum in double contrast. Appropriate spot images should be obtained to document normal and abnormal findings.

d. Fluoroscopy should be used to evaluate the esophagus, stomach, and duodenum after ingestion of low-density barium. Additional spot images may be used to document normal and abnormal findings. Manual or mechanical compression of the accessible portions of the stomach and duodenum may be used.

e. At the end of the examination, overhead images can be obtained as part of the routine protocol.

f. The quality control indicators specific to this study are:
   i. Adequate barium coating of the esophagus, stomach, and duodenum.
   ii. Adequate gaseous distention of the esophagus, stomach, and duodenum. Double-contrast views may be supplemented by prone and/or upright compression views of the stomach and the duodenum. If quality control indicators demonstrate that adequate barium coating of the stomach and duodenum cannot be achieved, compression views should be included in the examination to display as much anatomy and pathology as possible.

5. Water-soluble contrast examination

Water-soluble contrast may be preferred to barium when there is concern for perforation into the mediastinum or peritoneal cavity.

If the patient is at risk for aspiration, iso-osmolar or low osmolar contrast agents are recommended for use. In patients with possible esophageal perforation who are at risk for aspiration, barium may also be used.

a. Water-soluble contrast in concentration sufficient for fluoroscopic and plain radiographic visualization should be used. Risks of aspiration should be considered prior to the study.

b. Fluoroscopic observation of the esophagus, stomach, and duodenum should be performed, with specific attention to any areas of suspected leakage.
c. If no leak is identified or the study is inconclusive in patients with possible esophageal perforation, a single-contrast barium esophagram may provide additional diagnostic information [14,15]. In addition, prone positioning of the patient may be helpful to detect a leak.
d. Appropriate spot images should be taken to document normal and abnormal findings. At the end of the examination, overhead images can be obtained as part of the routine protocol.

6. Portable technique

Portable technique can be used when the patient is too unstable for examination in the fluoroscopy suite or when portable technique will not compromise examination accuracy:
a. Gastrostomy or jejunostomy tube placement and patency may be ascertained by using portable radiography after injecting the tube with water-soluble contrast at the bedside. The images must be reviewed by the radiologist prior to using the tube.
b. If the portable examination does not provide adequate diagnostic accuracy or confidence level, the patient should be brought to the fluoroscopy suite for a targeted problem solving examination.

7. The following quality control indicators should be applied to all esophagram and upper GI examinations:
a. When examinations are completed, patients should be held in the fluoroscopic area until the images have been reviewed by the physician.
b. An attempt should be made to resolve questionable radiologic findings before the patient leaves. If necessary, repeat targeted fluoroscopy should be performed for problem solving.
c. Radiologic, endoscopic, and pathologic findings should be correlated whenever feasible.

V. DOCUMENTATION

Reporting should be in accordance with the ACR Practice Parameter for Communication of Diagnostic Imaging Findings [19].

It is recommended that radiation dose data be recorded for all fluoroscopy procedures in accordance with the ACR Technical Standard for Management of the Use of Radiation in Fluoroscopic Procedures [20]. If patient dose information from an automated dosimetry system is not available, the fluoroscopic exposure time and the number of acquired spot images should be recorded in the patient’s medical record.

VI. EQUIPMENT SPECIFICATIONS

Examinations must be performed with fluoroscopic and radiographic equipment meeting all applicable federal, state, and local radiation standards. The equipment should provide diagnostic fluoroscopic image quality and recording capability (film, video, or digital). The equipment should be capable of producing kilovoltage greater than 100 kVp. Equipment necessary to compress and isolate accessible regions of the stomach and duodenum should be readily available.

Facilities should have the ability to deliver supplemental oxygen, to suction the oral cavity and the upper respiratory tract, and to respond to life-threatening emergencies that may accompany aspiration, allergic reaction to contrast agents, or reflux.

VII. RADIATION SAFETY IN IMAGING

Radiologists, medical physicists, registered radiologist assistants, radiologic technologists, and all supervising physicians have a responsibility for safety in the workplace by keeping radiation exposure to staff, and to society as a whole, “as low as reasonably achievable” (ALARA) and to assure that radiation doses to individual patients are appropriate, taking into account the possible risk from radiation exposure and the diagnostic image quality necessary to achieve the clinical objective. All personnel that work with ionizing radiation must understand the key principles of occupational and public radiation protection (justification, optimization of protection and
application of dose limits) and the principles of proper management of radiation dose to patients (justification, optimization and the use of dose reference levels)

Nationally developed guidelines, such as the ACR’s Appropriateness Criteria®, should be used to help choose the most appropriate imaging procedures to prevent unwarranted radiation exposure.

Facilities should have and adhere to policies and procedures that require varying ionizing radiation examination protocols (plain radiography, fluoroscopy, interventional radiology, CT) to take into account patient body habitus (such as patient dimensions, weight, or body mass index) to optimize the relationship between minimal radiation dose and adequate image quality. Automated dose reduction technologies available on imaging equipment should be used whenever appropriate. If such technology is not available, appropriate manual techniques should be used.

Additional information regarding patient radiation safety in imaging is available at the Image Gently® for children (www.imagegently.org) and Image Wisely® for adults (www.imagewisely.org) websites. These advocacy and awareness campaigns provide free educational materials for all stakeholders involved in imaging (patients, technologists, referring providers, medical physicists, and radiologists).

Radiation exposures or other dose indices should be measured and patient radiation dose estimated for representative examinations and types of patients by a Qualified Medical Physicist in accordance with the applicable ACR technical standards. Regular auditing of patient dose indices should be performed by comparing the facility’s dose information with national benchmarks, such as the ACR Dose Index Registry, the NCRP Report No. 172, Reference Levels and Achievable Doses in Medical and Dental Imaging: Recommendations for the United States or the Conference of Radiation Control Program Director’s National Evaluation of X-ray Trends. (ACR Resolution 17 adopted in 2006 – revised in 2009, 2013, Resolution 52).

VIII. QUALITY CONTROL AND IMPROVEMENT, SAFETY, INFECTION CONTROL, AND PATIENT EDUCATION

Policies and procedures related to quality, patient education, infection control, and safety should be developed and implemented in accordance with the ACR Policy on Quality Control and Improvement, Safety, Infection Control, and Patient Education appearing under the heading Position Statement on QC & Improvement, Safety, Infection Control, and Patient Education on the ACR website (http://www.acr.org/guidelines).

ACKNOWLEDGEMENTS

This practice parameter was revised according to the process described under the heading The Process for Developing ACR Practice Parameters and Technical Standards on the ACR website (http://www.acr.org/guidelines) by the Committee on Abdominal Imaging of the ACR Commission on Body Imaging and the Guidelines and Standards Committee of the ACR Commission on General, Small, and Rural Practice.

Principal Reviewers: Oleg M. Teytelboym, MD  
Eric M. Rubin, MD
