The American College of Radiology, with more than 30,000 members, is the principal organization of radiologists, radiation oncologists, and clinical medical physicists in the United States. The College is a nonprofit professional society whose primary purposes are to advance the science of radiology, improve radiologic services to the patient, study the socioeconomic aspects of the practice of radiology, and encourage continuing education for radiologists, radiation oncologists, medical physicists, and persons practicing in allied professional fields.

The American College of Radiology will periodically define new practice parameters and technical standards for radiologic practice to help advance the science of radiology and to improve the quality of service to patients throughout the United States. Existing practice parameters and technical standards will be reviewed for revision or renewal, as appropriate, on their fifth anniversary or sooner, if indicated.

Each practice parameter and technical standard, representing a policy statement by the College, has undergone a thorough consensus process in which it has been subjected to extensive review and approval. The practice parameters and technical standards recognize that the safe and effective use of diagnostic and therapeutic radiology requires specific training, skills, and techniques, as described in each document. Reproduction or modification of the published practice parameter and technical standard by those entities not providing these services is not authorized.

Revised 2023 (Resolution 36)*

ACR–ACOG–AIUM–SMFM–SRU PRACTICE PARAMETER FOR THE PERFORMANCE OF STANDARD DIAGNOSTIC OBSTETRICAL ULTRASOUND

PREAMBLE

This document is an educational tool designed to assist practitioners in providing appropriate radiologic care for patients. Practice Parameters and Technical Standards are not inflexible rules or requirements of practice and are not intended, nor should they be used, to establish a legal standard of care. For these reasons and those set forth below, the American College of Radiology and our collaborating medical specialty societies caution against the use of these documents in litigation in which the clinical decisions of a practitioner are called into question.

The ultimate judgment regarding the propriety of any specific procedure or course of action must be made by the practitioner considering all the circumstances presented. Thus, an approach that differs from the guidance in this document, standing alone, does not necessarily imply that the approach was below the standard of care. To the contrary, a conscientious practitioner may responsibly adopt a course of action different from that set forth in this document when, in the reasonable judgment of the practitioner, such course of action is indicated by variables such as the condition of the patient, limitations of available resources, or advances in knowledge or technology after publication of this document. However, a practitioner who employs an approach substantially different from the guidance in this document may consider documenting in the patient record information sufficient to explain the approach taken.

The practice of medicine involves the science, and the art of dealing with the prevention, diagnosis, alleviation, and treatment of disease. The variety and complexity of human conditions make it impossible to always reach the most appropriate diagnosis or to predict with certainty a particular response to treatment. Therefore, it should be recognized that adherence to the guidance in this document will not assure an accurate diagnosis or a successful outcome. All that should be expected is that the practitioner will follow a reasonable course of action based on current knowledge, available resources, and the needs of the patient to deliver effective and safe medical care. The purpose of this document is to assist practitioners in achieving this objective.

---

1 Iowa Medical Society and Iowa Society of Anesthesiologists v. Iowa Board of Nursing 831 N.W.2d 826 (Iowa 2013) Iowa Supreme Court refuses to find that the ACR Technical Standard for Management of the Use of Radiation in Fluoroscopic Procedures (Revised 2008) sets a national standard for who may perform fluoroscopic procedures in light of the standard’s stated purpose that ACR standards are educational tools and not intended to establish a legal standard of care. See also, Stanley v. McCarver, 63 P.3d 1076 (Ariz. App. 2003) where in a concurring opinion the Court stated that “published standards or guidelines of specialty medical organizations are useful in determining the duty owed or the standard of care applicable in a given situation” even though ACR standards themselves do not establish the standard of care.
I. INTRODUCTION

The clinical aspects contained in specific sections of this practice parameter (Introduction, Classification of Fetal Ultrasound Examinations, Specifications of the Examination, Equipment Specifications, and Fetal Safety) were revised collaboratively by the American College of Radiology (ACR), the American Institute of Ultrasound in Medicine (AIUM), the American College of Obstetricians and Gynecologists (ACOG), the Society for Maternal Fetal Medicine (SMFM), and the Society of Radiologists in Ultrasound (SRU). Recommendations for Qualifications and Responsibilities of Personnel, Written Request for the Examination, Documentation, and Quality Control and Improvement, Safety, Infection Control, and Patient Education vary among the organizations and are addressed by each separately.

Obstetrical ultrasound\(^2\) should be performed only when there is a valid medical reason, and the lowest possible acoustic output settings should be used to gain the necessary diagnostic information [1-3].

Although this practice parameter describes the key elements of standard ultrasound examinations in the first, second, and third trimesters of pregnancy, a more detailed fetal anatomic examination may be necessary in some cases, such as when an abnormality is found or suspected on the standard examination or in pregnancies at high risk for fetal anomaly [4]. In some cases, other imaging may be necessary as well.

Although it is not possible to detect all structural congenital anomalies with diagnostic ultrasound, adherence to the following practice parameters will increase the likelihood of detecting many fetal abnormalities.

II. CLASSIFICATION OF FETAL ULTRASOUND EXAMINATIONS

A. Standard First Trimester Ultrasound Examination

A standard obstetrical ultrasound examination in the first trimester includes evaluation of the presence, size, location, and number of gestational sac(s). The gestational sac is examined for the presence of yolk sac and embryo/fetus (a fetus is generally defined as greater than or equal to 10 weeks’ gestational age) [5]. When an embryo/fetus is detected, the crown rump length should be measured, and the presence or absence of cardiac activity should be recorded by cine clip or M-mode. The routine use of pulsed Doppler ultrasound to either document or “listen” to embryonic/fetal cardiac activity is discouraged [6]. The uterus, cervix, adnexa, and cul-de-sac region should be examined.

B. Standard Second or Third Trimester Ultrasound Examination

An obstetrical ultrasound in the second or third trimester includes an evaluation of fetal number, cardiac activity, presentation, amniotic fluid volume, placental position, placental cord insertion site, fetal biometry, anatomic survey, and growth. The patient’s cervix, uterus, and adnexa should be examined.

C. Limited Ultrasound Examination

A limited obstetric ultrasound examination is performed to answer a specific, acute clinical question when an immediate impact on management is anticipated and when time or other constraints make performance of a standard ultrasound impractical or unnecessary. If a limited obstetric ultrasound is performed on a patient who has not previously had a standard or detailed ultrasound examination, a subsequent standard or detailed ultrasound should be obtained where appropriate. In patients who require serial ultrasounds and have already had a standard or detailed scan, some will only need limited scans, whereas others will require standard or detailed follow-up examinations. Clinical judgement should be used to determine the proper type of ultrasound examination to perform and the appropriate frequency for follow-up ultrasound examinations [7].

D. Specialized Ultrasound Examination

\(^2\) The consensus of the committee was that the use of the terms “ultrasound” or “sonography” is at the discretion of each organization.
A detailed anatomic examination is performed for patients at risk for fetal anatomic or karyotypic abnormalities (including, but not limited to, advanced patient age, medical complications of pregnancy, or pregnancy after assisted reproductive technology) or when an anomaly is suspected on the basis of history, abnormal biochemical markers, cell-free DNA screening, or the results of either the limited or standard scan [4].

Other specialized ultrasound scans may include fetal echocardiogram, biophysical profile and fetal Doppler ultrasound, or additional biometric measurements including nuchal translucency (NT) and cervical length [8-14].

III. QUALIFICATIONS AND RESPONSIBILITIES OF PERSONNEL

See the ACR–SPR–SRU Practice Parameter for Performing and Interpreting Diagnostic Ultrasound Examinations [15].

IV. SPECIFICATIONS OF THE EXAMINATION

The written or electronic request for an obstetrical ultrasound examination should provide sufficient information to demonstrate the medical necessity of the examination and allow for its proper performance and interpretation.

Documentation that satisfies medical necessity includes 1) signs and symptoms and/or 2) relevant history (including known diagnoses). Additional information regarding the specific reason for the examination or a provisional diagnosis would be helpful and may at times be needed to allow for the proper performance and interpretation of the examination.

The request for the examination must be originated by a physician or other appropriately licensed health care provider. The accompanying clinical information should be provided by a physician or other appropriately licensed health care provider familiar with the patient’s clinical problem or question and consistent with the state’s scope of practice requirements. (ACR Resolution 35 adopted in 2006 – revised in 2016, Resolution 12-b)

A. Standard First Trimester Ultrasound Examination

1. Indications for first trimester³ ultrasound examinations include, but are not limited to:
   
   a. Confirmation of the presence of an intrauterine pregnancy [16-18]
   b. Confirmation of cardiac activity [19-23]
   c. Estimation of gestational age [24-26]
   d. Diagnosis or evaluation of multiple gestations including determination of chorionicity and amnionicity [27,28]
   e. Evaluation of a suspected ectopic or abnormally implanted pregnancy [29,30]
   f. Evaluating the cause of vaginal bleeding
   g. Evaluation of pelvic pain
   h. Evaluation of suspected gestational trophoblastic disease [31]
   i. Measuring the NT and nasal bone when part of a screening program for fetal aneuploidy
   j. Assessing for fetal anomalies detectable in the first trimester, such as anencephaly [9,10,32-40]
   k. Imaging as an adjunct to chorionic villus sampling, embryo transfer, and localization and removal of an intrauterine device
   l. Evaluation of pelvic masses and/or uterine abnormalities

2. Imaging parameters

   Scanning in the first trimester may be performed transabdominally, transvaginally, or a combination of both.

   If a transabdominal examination is not definitive, a transvaginal scan is recommended.

³For the purpose of this document, first trimester represents 1w-13w + 6d.
a. The uterus (including the cervix) and adnexa should be evaluated for the presence of a gestational sac. If a gestational sac is seen, the location, size, and shape should be documented. The gestational sac should be evaluated for the presence or absence of a yolk sac and embryo/fetus. If an embryo/fetus is identified, the crown-rump length should be measured [17,24-26,41].

A definitive diagnosis of intrauterine pregnancy can be made when an intrauterine gestational sac containing a yolk sac or embryo/fetus with or without cardiac activity is visualized. In a very early intrauterine pregnancy, a small, eccentric intrauterine fluid collection with an echogenic rim can be seen before the yolk sac and embryo. In the absence of sonographic signs of ectopic pregnancy, the fluid collection is highly likely to represent an intrauterine gestational sac. Follow-up ultrasound and/or serial determination of patient serum beta human chorionic gonadotropin levels are appropriate in pregnancies of undetermined location to avoid inappropriate intervention in a potentially viable early pregnancy [16,20,21].

Caution should be used in making the presumptive diagnosis of a gestational sac in the absence of a definite yolk sac or embryo. If the embryo is not identified, the mean sac diameter may be useful for determining the timing of ultrasound follow-up. However, the crown-rump length is a more accurate indicator of gestational age than the mean gestational sac diameter.

b. The presence or absence of cardiac activity should be documented with a cine clip or M-mode [6].

With transvaginal scans, cardiac motion is usually observed when the embryo is 2 mm or greater in length; if an embryo less than 7 mm in length is seen without cardiac activity, a subsequent scan in one week is recommended to ensure that the pregnancy is nonviable [19-23].

c. Fetal number should be documented.

Amnionicity and chorionicity should be documented for all multiple gestations [27].

d. In the later first trimester, fetal anatomy should be assessed and include the cranium, midline falx, choroid plexus, profile including nasal bone, lungs, stomach, situs, abdominal umbilical cord insertion, and the presence of limbs. A four-chamber view should be evaluated if technically feasible. [32-36,42-44].

e. The nuchal region should be imaged, and abnormalities such as cystic hygroma should be documented.

A precise NT measurements should be obtained in these scenarios:

1. If a measurement is required as part of aneuploidy risk calculation (in conjunction with serum analytes). In this setting, it is important that the practitioner measure the NT according to established guidelines. A quality assessment program is recommended to ensure that false-positive and false-negative results are kept to a minimum [9,10].

2. If the NT appears subjectively enlarged. In practices in which cell-free DNA is used primarily for aneuploidy screening, an enlarged NT may be considered a sonographic marker of structural, genetic, or syndromic abnormalities.

Guidelines for NT measurement:

i. The margins of the NT edges must be clear with the angle of insonation perpendicular to the NT line.

ii. The fetus must be in the midsagittal plane. The tip of the nose, palate, and diencephalon should be seen.

iii. The image must be magnified so that it is filled by the fetal head, neck, and upper thorax.

iv. The fetal neck must be in a neutral position, with the head in line with the spine, not flexed and not hyperextended.

v. The amnion must be seen as separate from the NT line.
vi. The (+) calipers on the ultrasound must be used to perform the NT measurement.
vii. Electronic calipers must be placed on the inner borders of the nuchal line with none of the horizontal crossbar itself protruding into the space.
viii. The calipers must be placed perpendicular to the long axis of the fetus.
ix. The measurement must be obtained at the widest space of the NT.

Figure 1. Ultrasound image of NT measurement

![Ultrasound image of NT measurement](image)

Figure 2. Diagram for the NT measurement

![Diagram for the NT measurement](image)

f. The uterus, including the cervix, adnexal structures, and cul-de-sac, should be evaluated. Abnormalities should be imaged and documented.

The presence, location, appearance, and size of adnexal masses should be documented. The presence and number of leiomyomata should be documented. The measurements of the largest or any potentially clinically significant leiomyomata should be documented. The cul-de-sac should be evaluated for the presence or absence of fluid. Uterine anomalies should be documented.

B. Standard Second and Third Trimester Ultrasound Examination [17]

1. These examinations are commonly performed to assess fetal anatomy and biometry. Other indications include but are not limited to:

   a. Screening for fetal anomalies [45-50]
   b. Evaluation of fetal anatomy [51-60]
   c. Estimation of gestational age [45]
d. Evaluation of suspected multiple gestation

e. Evaluation of cervical length [11-13, 61-65]

f. Evaluation of fetal growth [66-69]

g. Evaluation of significant discrepancy between uterine size and clinical dates

h. Determination of fetal presentation

i. Evaluation of fetal well-being [43]

j. Suspected amniotic fluid abnormalities [70-72]

k. Evaluation of premature rupture of membranes and/or premature labor

l. Evaluation of vaginal bleeding

m. Evaluation of abdominal or pelvic pain

n. Suspected placental abruption

o. Suspected fetal death

p. Follow-up evaluation of a fetal anomaly [73]

q. Evaluation/follow-up of placental appearance and location. Includes suspected placenta previa, vasa previa, and evaluation of placenta accreta spectrum) [74]

r. Adjunct to amniocentesis or other procedure

s. Adjunct to external cephalic version

t. Evaluation of suspected gestational trophoblastic disease

u. Evaluation of pelvic mass

v. Suspected uterine anomalies

In certain clinical circumstances, a more detailed examination of fetal anatomy may be indicated [75].

2. Imaging parameters for a standard fetal examination

a. Fetal cardiac activity (by cine clip or M-mode), fetal number, and presentation should be documented.

Abnormal heart rate and/or rhythm should be documented.

Multiple gestations require the documentation of additional information: chorionicity, amnionicity, comparison of fetal sizes, evaluation of amniotic fluid volume in each gestational sac, and fetal genitalia (when visualized).

b. A qualitative or semiquantitative estimate of amniotic fluid volume should be documented.

Although it is acceptable for experienced examiners to qualitatively estimate amniotic fluid volume, semiquantitative methods have also been described for this purpose (eg, amniotic fluid index [AFI], single deepest pocket, and 2-D pocket). In assessing oligohydramnios, the deepest vertical pocket (<2 cm) is preferred over AFI (≤5 cm) because it results in fewer obstetrical interventions without a significant difference in perinatal outcome, and single deepest pocket should be at least 1 cm wide [70-72, 76, 77]. Polyhydramnios (deepest vertical pocket ≥8 cm or AFI ≥24 cm) may be associated with other pregnancy complications [76].

c. The placental location, appearance, and relationship to the internal cervical os should be documented.

In patients who have had one or more prior cesarean deliveries, a detailed evaluation of the placental location and attachment in the lower uterine segment should be performed looking for signs of placenta accreta spectrum. The umbilical cord should be imaged, and the number of vessels in the cord documented. The placental cord insertion site should be documented when technically possible [78, 79].

It is recognized that apparent placental position early in pregnancy may not correlate well with its location at the time of delivery.

Transvaginal ultrasound should be performed if the relationship between the cervix and the placenta cannot be assessed.
Vasa previa, defined as fetal vessels in close proximity to the cervix (typically within 2 cm of the internal cervical os), is associated with a high risk of fetal morbidity and mortality if not diagnosed prior to labor [80-82]. Risk factors for vasa previa include resolving low-lying/placenta previa, bilobed/succenturiate lobe of the placenta, velamentous cord insertion, multiple gestations, and in vitro fertilization [83]. Non-visualization of the PCI may also be associated with vasa previa. Transvaginal ultrasound with color and pulsed Doppler (to document fetal vessels) should be performed in scenarios in which vasa previa is suspected [84].

d. Gestational age assessment

First-trimester crown-rump measurement is the most accurate means for sonographic dating of pregnancy. Beyond this period, a variety of sonographic parameters such as biparietal diameter, abdominal circumference, and femoral diaphysis length can be used to estimate gestational age. It should be noted that abdominal circumference is the least reliable of these measurements for estimating gestational age [85,86]. The variability of gestational age estimation, however, increases with advancing pregnancy. Significant discrepancies between gestational age and fetal measurements may suggest the possibility of a fetal growth abnormality [66-69].

Gestational age assessment by ultrasound in the early second trimester (between 14 0/7 weeks’ and 21 6/7 weeks’ gestation) is based on a composite of fetal biometric measurements and has an accuracy of ±7-10 days [87].

The pregnancy should NOT be redated after an accurate earlier scan has been performed and is available for comparison [88,89].

i. Biparietal diameter is measured at the level of the thalami and cavum septi pellucidi [90]. The cerebellar hemispheres should not be visible in this scanning plane. The measurement is typically measured from the outer edge of the proximal skull to the inner edge of the distal skull.

The head shape may be elongated (dolichocephaly) or rounded (brachycephaly) as a normal variant. Under these circumstances, certain variants of normal fetal head development may make measurement of the head circumference more reliable than biparietal diameter for estimating gestational age.

ii. Head circumference is measured at the same level as the biparietal diameter, around the outer perimeter of the bony calvarium, excluding subcutaneous tissues of the skull. This measurement is not affected by head shape.

iii. Femoral diaphysis length can be reliably used after 14 weeks’ gestational age. The long axis of the femoral shaft is most accurately measured with the beam of insonation being perpendicular to the shaft, excluding the distal femoral epiphysis.

iv. Abdominal circumference or average abdominal diameter should be determined at the skin line on a true transverse view at the level of the junction of the umbilical vein, portal sinus, and fetal stomach when visible.

e. Fetal weight estimation

Fetal weight can be estimated from measurements such as the biparietal diameter, head circumference, abdominal circumference or average abdominal diameter, and femoral diaphysis length [91,92]. Results from various prediction models can be subsequently compared to fetal weight percentiles from published nomograms [66-69,93-95].

If previous studies have been performed, appropriateness of growth should also be documented. Scans
for growth evaluation should be performed no more frequently than 2-week intervals. A shorter scan interval may result in confusion as to whether measurement changes are truly due to growth as opposed to technical variations [96-99].

Currently, even the best fetal weight prediction methods can yield errors as high as ±15% [100].

f. Patient anatomy

Evaluation of the uterus, adnexal structures, and cervix should be performed.

The presence, location, and size of adnexal masses and the presence of at least the largest and potentially clinically significant leiomyomata should be documented. It is not always possible to image the normal ovaries during the second and third trimesters.

If the cervix appears abnormal (shortened or funneled) or is not adequately visualized during the transabdominal ultrasound, a transvaginal scan is recommended [11,12,63,101].

If a referring health provider desires a precise cervical-length measurement, a transvaginal measurement of the cervix should be performed [11,12,61-65].

A midline lower uterine segment contraction may obscure the internal os, giving the false impression of a longer endocervical canal. Excessive manual pressure with the ultrasound transducer may also falsely elongate the cervix.

Table 1. Criteria for cervical-length measurement

</tr>
<tr>
<td>Shortest, best of 3 measurements is reported.</td>
</tr>
<tr>
<td>Dynamic cervical shortening- examination time 3 minutes and/or suprapubic/fundal pressure.</td>
</tr>
</tbody>
</table>
g. Fetal anatomic survey

Fetal anatomy, as described in this document, may be adequately assessed by ultrasound after approximately 18 weeks gestational age. It may be possible to document normal structures before this time, although some structures can be difficult to visualize because of fetal size, position, movement, abdominal scars, or increased patient body mass index [102-105]. A second or third trimester scan may pose technical limitations for an anatomic evaluation due to imaging artifacts from acoustic shadowing. When this occurs, the report of the ultrasound examination should document the nature of this technical limitation. A follow-up examination may be helpful.

The following areas of assessment represent the minimal elements of a standard examination of fetal anatomy. A more detailed fetal anatomic examination may be necessary if an abnormality or suspected abnormality is found on the standard examination.

i. Head, face, and neck
   - Lateral cerebral ventricles
   - Choroid plexus
   - Midline falx
   - Cavum septi pellucidi
   - Cerebellum
   - Cisterna magna
   - Upper lip
   - Profile (including nasal bone)

A measurement of the nuchal fold may be helpful during a specific age interval (approximately 16-20 weeks gestational age) to assess the risk of aneuploidy [106].

ii. Chest
    - Heart [107]
      - Four-chamber view
      - Heart size, position, and situs
      - Left ventricular outflow tract
      - Right ventricular outflow tract
      - Three-vessel view and three-vessel trachea view, if technically feasible [55-60]

iii. Abdomen
    - Stomach (presence, size, and situs)
    - Bowel
Kidneys
Urinary bladder
Umbilical cord insertion site into the fetal abdomen
Umbilical cord vessel number

iv. Spine
   Cervical, thoracic, lumbar, and sacral spine

v. Extremities
   Presence of legs and arms
   Presence of hands and feet

vi. External Genitalia
   If medically indicated or the patient wants to know

V. DOCUMENTATION

Reporting should be in accordance with the ACR Practice Parameter for Communication of Diagnostic Imaging Findings [96].

Adequate documentation of the study is essential for high-quality patient care. There should be a permanent record of the ultrasound examination and its interpretation. Comparison with prior relevant imaging studies may prove helpful. Images of all appropriate areas, both normal and abnormal, should be recorded. Variations from normal size should generally be accompanied by measurements. Images should be labeled with the patient identification, facility identification, examination date, and image orientation, and anatomic structure recorded. An official interpretation (final report) of the ultrasound examination should be included in the patient’s medical record. Retention of the ultrasound examination images should be consistent both with clinical need and with relevant legal and local health care facility requirements [95].

VI. EQUIPMENT SPECIFICATIONS

Equipment performance monitoring should be in accordance with the ACR–AAPM Technical Standard for Diagnostic Medical Physics Performance Monitoring of Real Time Ultrasound Equipment [15].

Obstetrical ultrasound examinations should be conducted with modern imaging systems, using a transabdominal and/or transvaginal approach. The choice of transducer frequency is a tradeoff between beam penetration and resolution. In most patients, an abdominal transducer of \( \geq 3 \) MHz allows sufficient penetration while providing adequate resolution. During early pregnancy, transvaginal ultrasound may provide superior resolution while still allowing adequate penetration.

VIII. QUALITY CONTROL AND IMPROVEMENT, SAFETY, INFECTION CONTROL, AND PATIENT EDUCATION

Policies and procedures related to quality, patient education, infection control, and safety should be developed and implemented in accordance with the ACR Policy on Quality Control and Improvement, Safety, Infection Control, and Patient Education appearing under the heading Position Statement on QC & Improvement, Safety, Infection Control, and Patient Education on the ACR website (https://www.acr.org/Advocacy-and-Economics/ACR-Position-Statements/Quality-Control-and-Improvement).

All probes should be cleaned after use. Vaginal probes should be covered by a protective sheath prior to insertion. Following the examination, the sheath should be disposed of and the probe cleaned with a high-level disinfectant according to the manufacturer and local infectious disease recommendation.

Fetal Safety
Diagnostic ultrasound studies of the embryo/fetus are generally considered to be safe during pregnancy [1,2,108-111]. This diagnostic procedure should be performed only when there is a valid medical indication, and the lowest possible acoustic output setting should be used to gain the necessary diagnostic information under the “as low as reasonably achievable” (ALARA) principle [1-3,6,108-111].

A thermal index for soft tissue (TIs) should be used at <10 weeks’ gestation and a thermal index for bone should be used at ≥10 weeks’ gestation when bone ossification is evident [3,112]. A TI ratio of 0.7 or less should be used for obstetrical scanning. Higher acoustic outputs should only be used if needed to obtain diagnostic quality images. In keeping with the ALARA principle, spectral Doppler ultrasound should not be used unless clinically indicated [6,101].

The promotion, selling, or leasing of ultrasound equipment for making “keepsake fetal videos” is considered by the U.S. Food and Drug Administration (FDA) to be an unapproved use of a medical device [113-115]. Use of a diagnostic ultrasound system for these purposes, without a physician’s order, may be in violation of state laws or regulations [102].

ACKNOWLEDGEMENTS

This practice parameter was revised according to the process described under the heading The Process for Developing ACR Practice Parameters and Technical Standards on the ACR website (https://www.acr.org/Clinical-Resources/Practice-Parameters-and-Technical-Standards) by the Committee on Practice Parameters – Ultrasound of the ACR Commission on Ultrasound, in collaboration with the AIUM, the ACOG, the SMFM, and the SRU.

Writing Committee - members represent their societies in the initial and final revision of this practice parameter
